

Python Data Types

[< Previous](#)[Next >](#)

Built-in Data Types

In programming, data type is an important concept.

Variables can store data of different types, and different types can do different things.

Python has the following data types built-in by default, in these categories:

Text Type:	<code>str</code>
Numeric Types:	<code>int</code> , <code>float</code> , <code>complex</code>
Sequence Types:	<code>list</code> , <code>tuple</code> , <code>range</code>
Mapping Type:	<code>dict</code>
Set Types:	<code>set</code> , <code>frozenset</code>
Boolean Type:	<code>bool</code>
Binary Types:	<code>bytes</code> , <code>bytearray</code> , <code>memoryview</code>
None Type:	<code>NoneType</code>

Getting the Data Type

You can get the data type of any object by using the `type()` function:

Example

Get your own Python Server

Print the data type of the variable x:

```
x = 5
print(type(x))
```

Try it Yourself »

Setting the Data Type

In Python, the data type is set when you assign a value to a variable:

Example	Data
x = "Hello World"	str
x = 20	int
x = 20.5	float
x = 1j	comp
x = ["apple", "banana", "cherry"]	list
x = ("apple", "banana", "cherry")	tuple
x = range(6)	range
x = {"name" : "John", "age" :	dict

COLOR
PICKER

36}	
x = {"apple", "banana", "cherry"}	set
x = frozenset({"apple", "banana", "cherry"})	frozer
x = True	bool
x = b"Hello"	bytes
x = bytearray(5)	bytea
x = memoryview(bytes(5))	memc
x = None	None1

Python Tutorial

If you want to specify the data type, you can use the following constructor functions:

ADVERT

[Python HOME](#)[Python Intro](#)[Python Get Started](#)[Python Syntax](#)[Python Comments](#)[Python Variables](#)[Python Data Types](#)[Python Numbers](#)[Python Casting](#)[Python Strings](#)[Python Booleans](#)[Python Operators](#)[Python Lists](#)[Python Tuples](#)[Python Sets](#)[Python Dictionaries](#)[Python If...Else](#)[Python Match](#)[Python While Loops](#)[Python For Loops](#)[Python Functions](#)[Python Decorators](#)[Python Range](#)[Python Lambda](#)[Python Arrays](#)[Python OOP](#)[Python Classes / Objects](#)

Example	Data
<code>x = str("Hello World")</code>	str
<code>x = int(20)</code>	int
<code>x = float(20.5)</code>	float
<code>x = complex(1j)</code>	comp
<code>x = list(("apple", "banana", "cherry"))</code>	list
<code>x = tuple(("apple", "banana", "cherry"))</code>	tuple
<code>x = range(6)</code>	range
<code>x = dict(name="John", age=36)</code>	dict
<code>x = set(("apple", "banana", "cherry"))</code>	set
<code>x = frozenset(("apple", "banana", "cherry"))</code>	frozer
<code>x = bool(5)</code>	bool
<code>x = bytes(5)</code>	bytes
<code>x = bytearray(5)</code>	bytea
<code>x = memoryview(bytes(5))</code>	memc

[REMO](#)

Exercise ?

If `x = 5` , what is a correct syntax for printing the data type of the variable `x` ?
