

tf.compat.v1.global_variables Stay organized with collections Save and categorize content based on your preferences.

https://www.tensorflow.org/api_docs/python/tf/compat/v1/global_variables

Returns global variables.

Function Signatures

```
tf.compat.v1.global_variables( scope=None )  
Variable()
```

Code Examples

```
tf.compat.v1.global_variables(  
    scope=None  
)
```

```
tf.compat.v1.global_variables(  
    scope=None  
)
```

Documentation

Returns global variables.

Migrate to TF2

Not compatible with eager execution and `tf.function`. In particular, Graph collections are deprecated in TF2. Instead please create a `tf.Module` container for all your model state, including variables. You can then list all the variables in your `tf.Module` through the `variables` attribute.

Description

Used in the notebooks

- Validating correctness & numerical equivalence
- Migrating model checkpoints

Global variables are variables that are shared across machines in a distributed environment. The `Variable()` constructor or `get_variable()` automatically adds new variables to the graph collection `GraphKeys.GLOBAL_VARIABLES`.

This convenience function returns the contents of that collection.

An alternative to global variables are local variables. See `tf.compat.v1.local_variables`

Returns
