

# quantize#

<https://pytorch.org/docs/stable/generated/torch.ao.quantization.quantize.html>

## Description:

Quantize the input float model with post training static quantization. First it will prepare the model for calibration, then it calls `run_fn` which will run the calibration step, after that we will convert the model to a quantized model. `model` – input float model `run_fn` – a calibration function for calibrating the prepared model `run_args` – positional arguments for `run_fn`

## Function Signature

---

```
class torch.ao.quantization.quantize(model, run_fn,  
run_args, mapping=None, inplace=False)[source]#
```

Parameters

Returns

## Returns:

Quantized model.

# Detailed Documentation

---

## Documentation

Quantize the input float model with post training static quantization.

First it will prepare the model for calibration, then it calls `run_fn` which will run the calibration step, after that we will convert the model to a quantized model.

`model` – input float model

`run_fn` – a calibration function for calibrating the prepared model

`run_args` – positional arguments for `run_fn`

`inplace` – carry out model transformations in-place, the original module is mutated

`mapping` – correspondence between original module types and quantized counterparts
